

Wavelength Stealing: An Opportunistic Approach to Channel Sharing in Multi-chip Photonic Interconnects

Arslan Zulfiqar (UW - Madison), Pranay Koka, Herb Schwetman (Oracle Labs), Mikko Lipasti (UW - Madison), Xuezhe Zheng, and Ashok V. Krishnamoorthy (Oracle Labs)

Problem: What is the "best" topology design for photonic substrates?

Point-to-Point or Channel sharing

Extra ring-resonators on shared wavelengths lead to higher laser power consumption

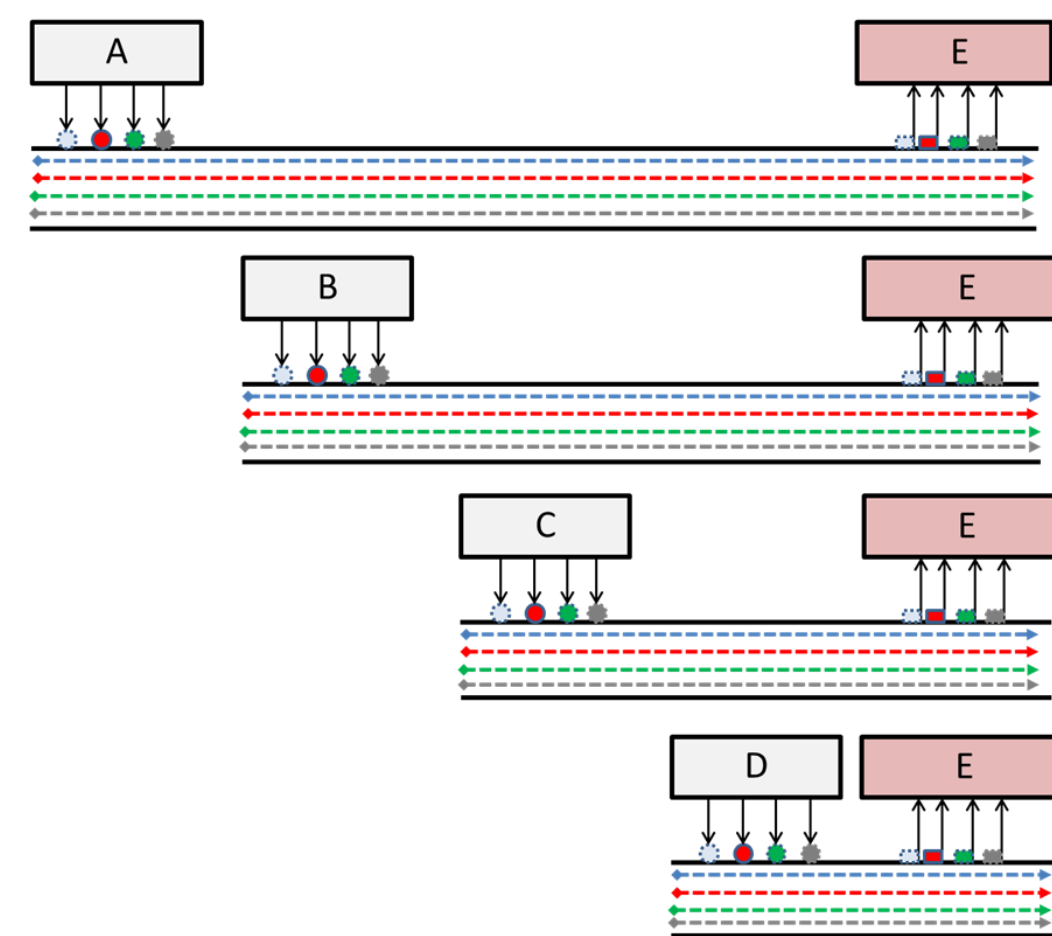

Photonic networks are static power dominated: laser, ring-resonator tuning power

Efficiencies of WDM lasers: 1-5%

Fixed input laser-power budget for all designs

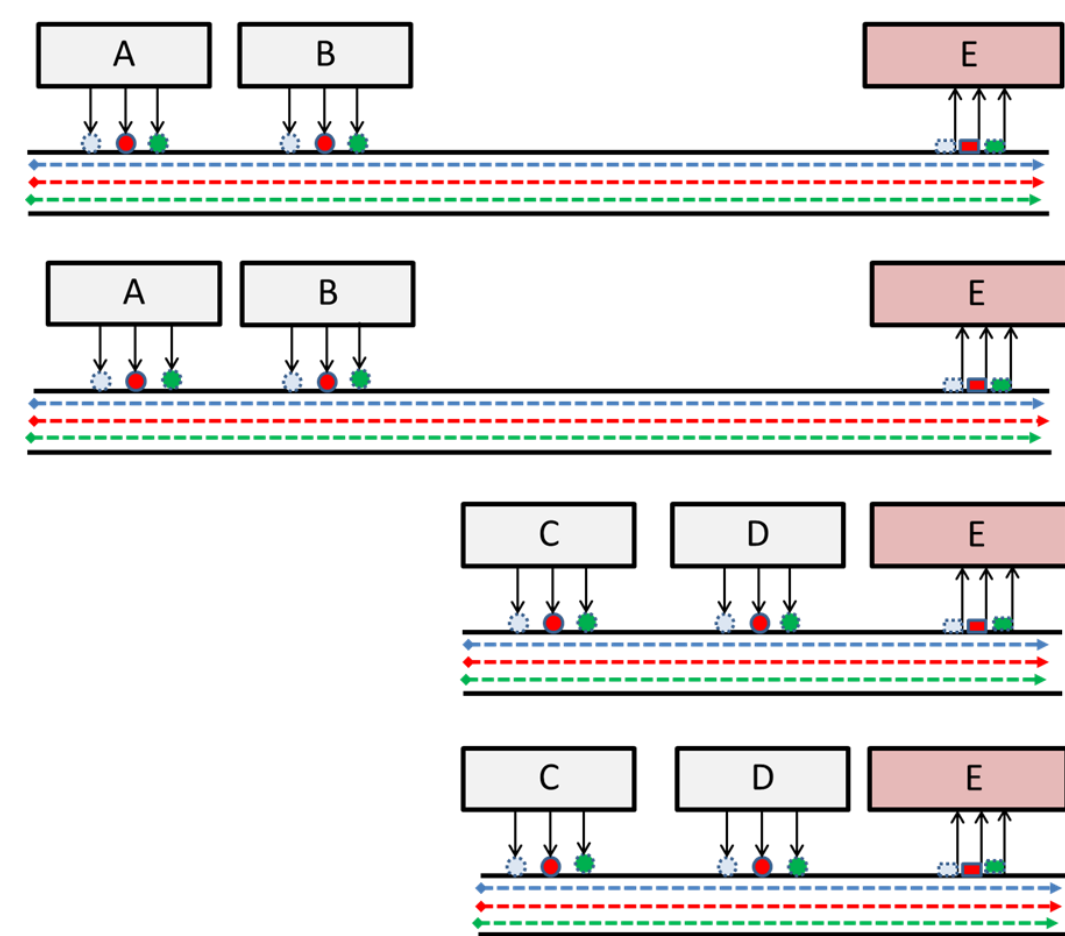

IMPLICATIONS OF LASER POWER BUDGET

P2P (unshared)

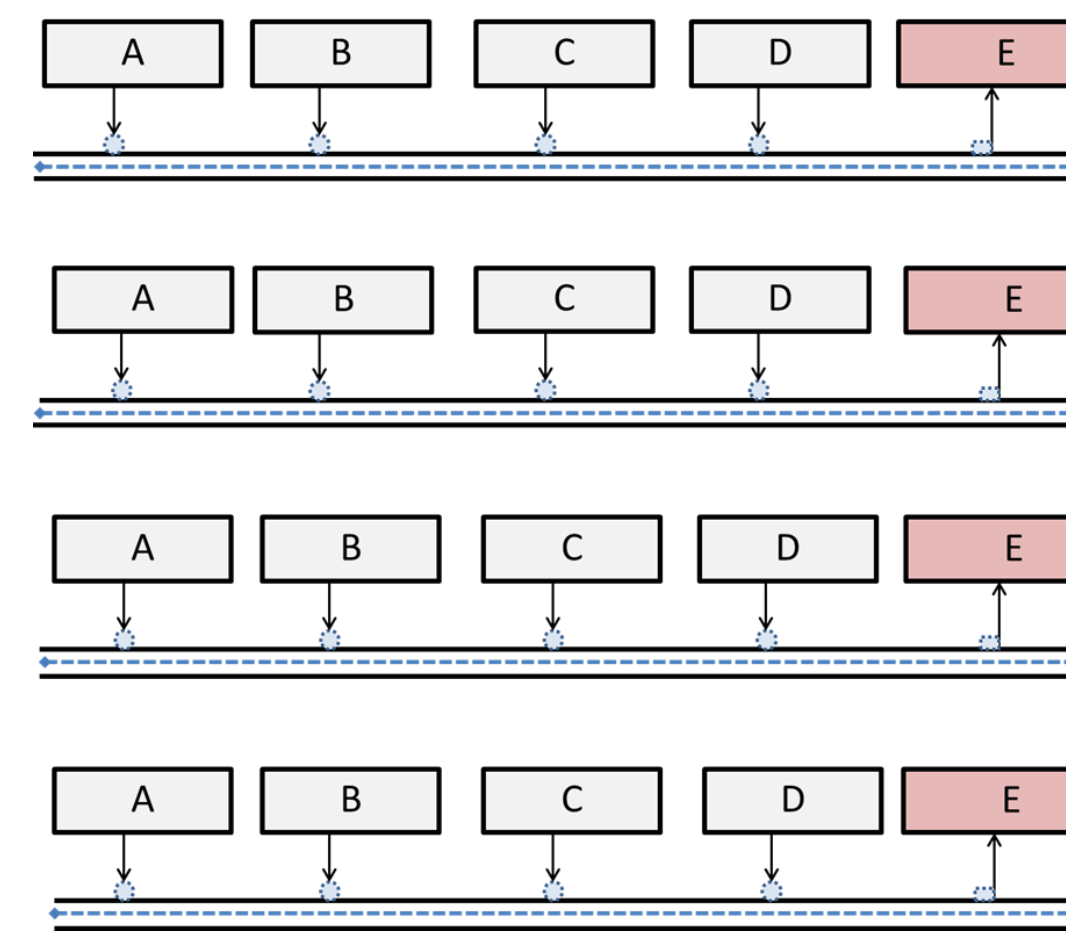

All-to-All traffic
• 4 x 4b/cycle
= 16b/cycle
Permutation traffic
• 4b/cycle

2-way sharing

All-to-All traffic
• 4 x 3b/cycle
= 12b/cycle
Permutation traffic
• 6b/cycle

4-way sharing

All-to-All traffic
• 4 x 1b/cycle
= 4b/cycle
Permutation traffic
• 4b/cycle

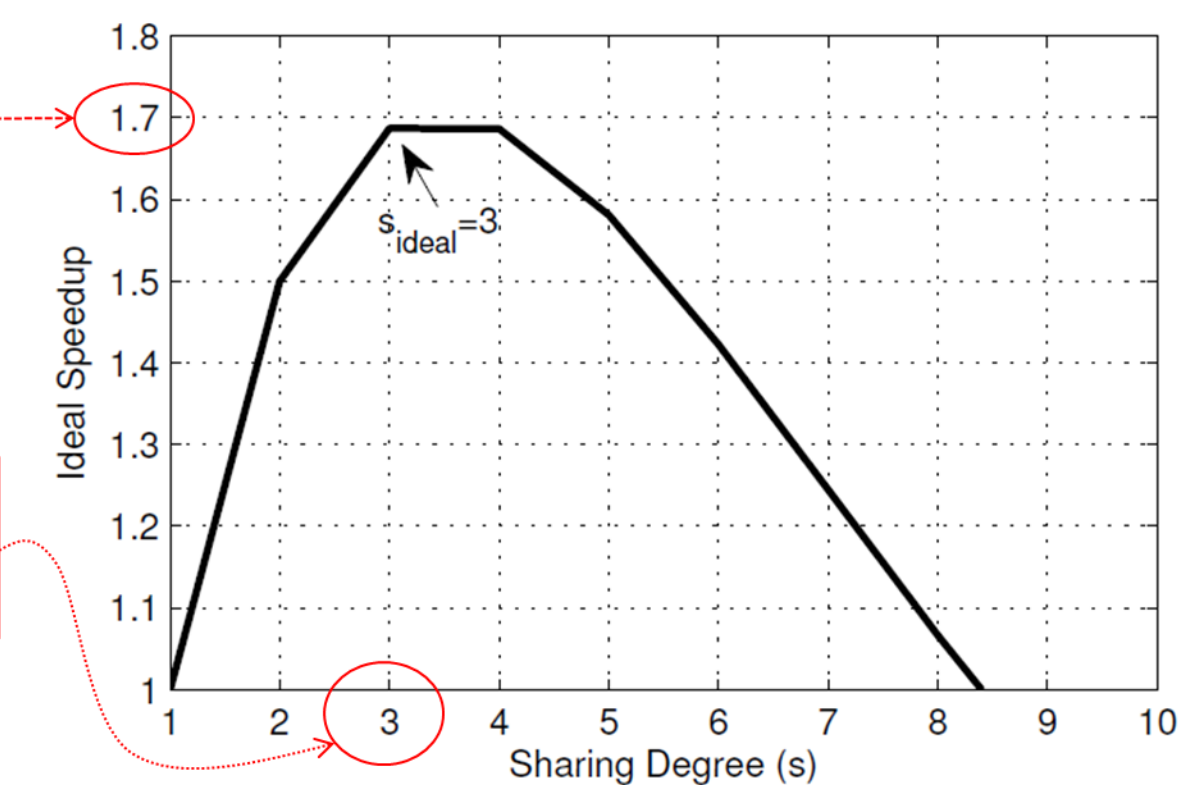

Increasing sharing degree: 's'

• Reduces effective capacity 😞

• Increases peak N-N BW followed by drop-off 😊

Optimal sharing gain
~ 1.70x

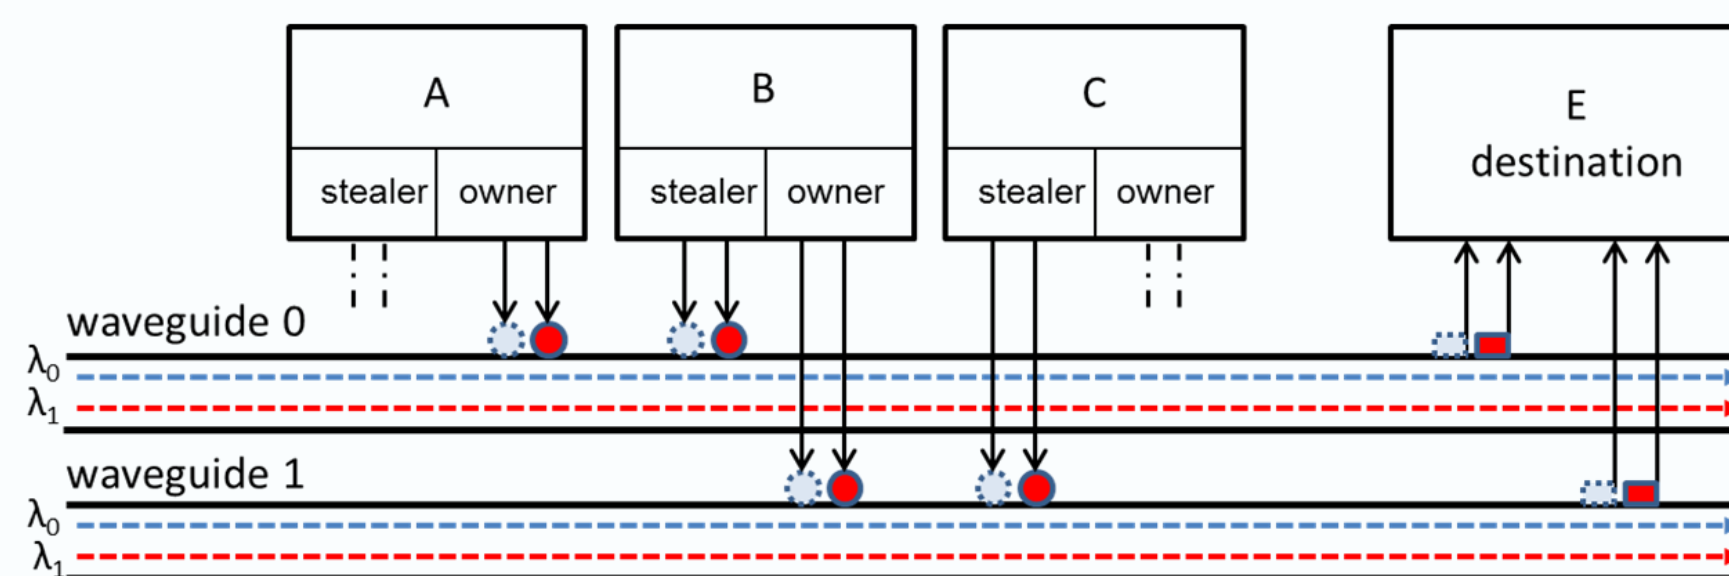

Optimal sharing degree
 $s_{ideal} = 3$

WAVELENGTH STEALING ARCHITECTURE

- Same topology as the P2P network: N^2 channels
- Every channel has **one owner** and **one or more stealers**

2-way stealing

- **Owner node**
 - Guaranteed non-blocking access
- **Stealer node**
 - Arbitration-free access on an owner's channel: possible packet corruption
 - Notification to halt stealing when channel busy
- **Destination node**
 - Corrupted phit: perform correction
 - Valid phit: identify sender (owner or stealer?)

- **Two Designs:**
 - Abort
 - (+) Fewer waveguides
 - (-) Conservative performance
 - (-) More ring-resonators
 - Sense
 - (+) Aggressive performance
 - (+) Fewer ring-resonators
 - (-) More waveguides
